

# **GOAL: BRING UP AND TEST BOARD 4**

## **The seven steps for this Project- : `**

### **1. Completing the plan of record (POR)**

- For this particular board, we have to make a 4 layer sensor shield which will have a number of sensors connected to it along with some new footprints and symbols. This sensor shield will then be integrated with my arduino board and it will be made functional using code written on it.
- Six different sensor and four different components have been integrated on our sensor shield which are- :

- Heartbeat sensor
- Temperature-humidity sensor
- Hall Effect magnetic field sensor
- CO, carbon monoxide sensor
- Microphone
- 4 smart LEDs
- Buzzer
- 12-bit DAC
- 16-bit ADC

The datasheets of each and every component have been checked and analyzed for which separate connections to be added simultaneously with sensors and components to utilize it better on our design. Also as part of the plan, DHT11 and MQ7 were to be placed on the female socket and no separate footprint and symbols were needed for these sensors. So 4 pin female headers footprints and symbols were one of the requirements to make and place on the design to integrate with these both sensors.

- Also to test some cases and for debugging proposes, some test points or LEDs should be considered before going to layout part.

**Rough sketch before schematic**

## **2. Completing the preliminary bill of materials (BOM)**

The list of materials includes many commodity parts such as capacitors and resistors, also non-commodity parts such as 16bit ADC1115, 12 bit DAC MCP4725, Ambient Light sensor (ALS-PT19-315C/L177/TR8), Microphone (CMEJ-0415-42-P), Smart LEDs (IN-PI55QATPRPGBPW-60), Buzzer (AT-1224-TWT-5V-2-R), and some male pin headers as the preliminary Bill of materials.

## **3. Completing the final schematic capture and final BOM**

Ultimately, the schematic was drawn with the planned approach along mentioned in the plan with certain changes wherever needed. Later the final BOM was taken from the schematic which is shown below.

Parts	Description	Designator	Footprint	LibRef	Quantity	LCSC Part#

## Final BOM

### 4. Completing the board layout and order all the parts.

After the schematic, the board layout part was completed with better routing as possible and short traces of the cross under path connections to reduce the noise as much as possible. (The schematic and layout are both attached on the later section of this report).

### 5. Completing the assembly.

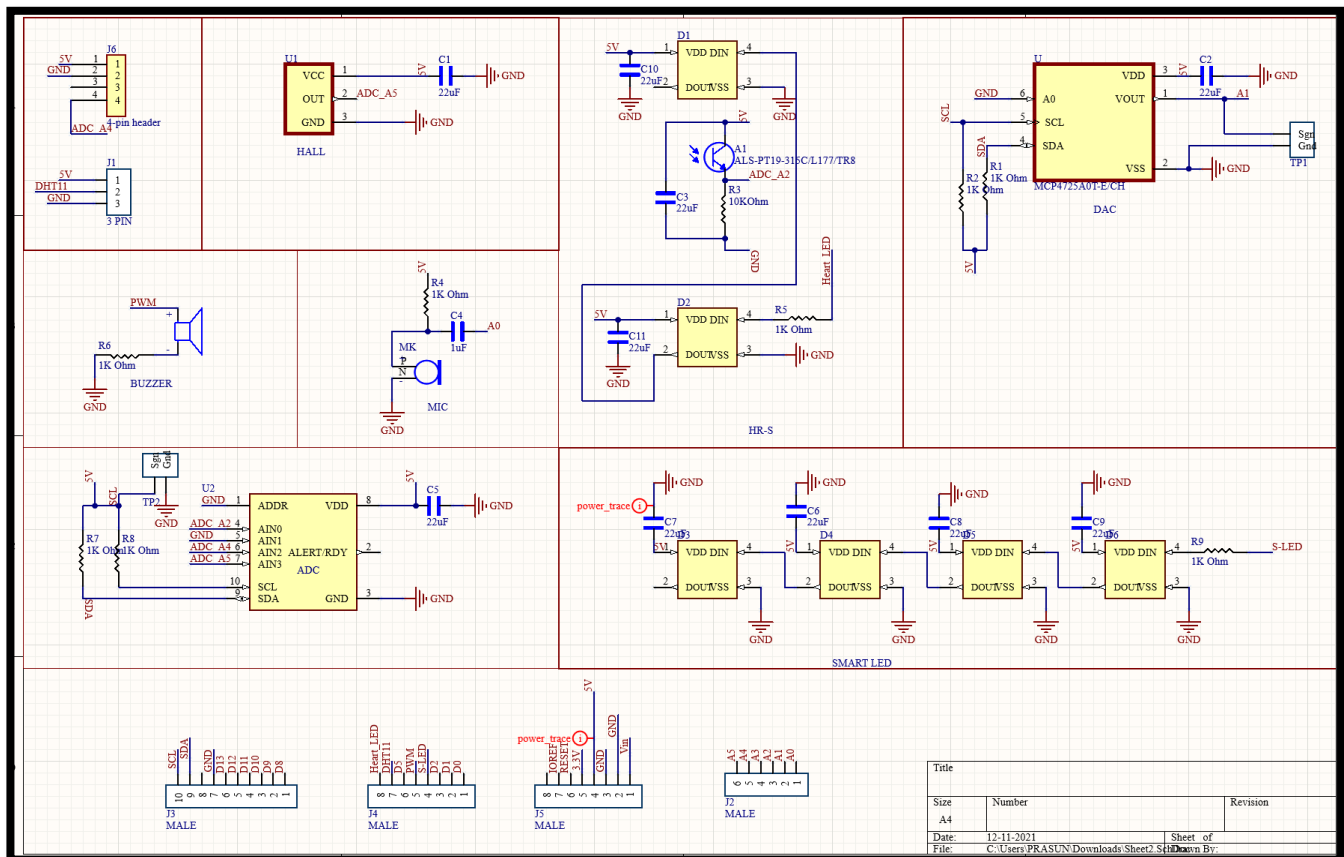

For this board, one of the main tasks was to assemble the board ourselves. So we had taken the required components and soldered ourselves and check the connectivity after soldering to make sure it was solder correctly.

### 6. Completing the bring up, Troubleshoot, and final test.

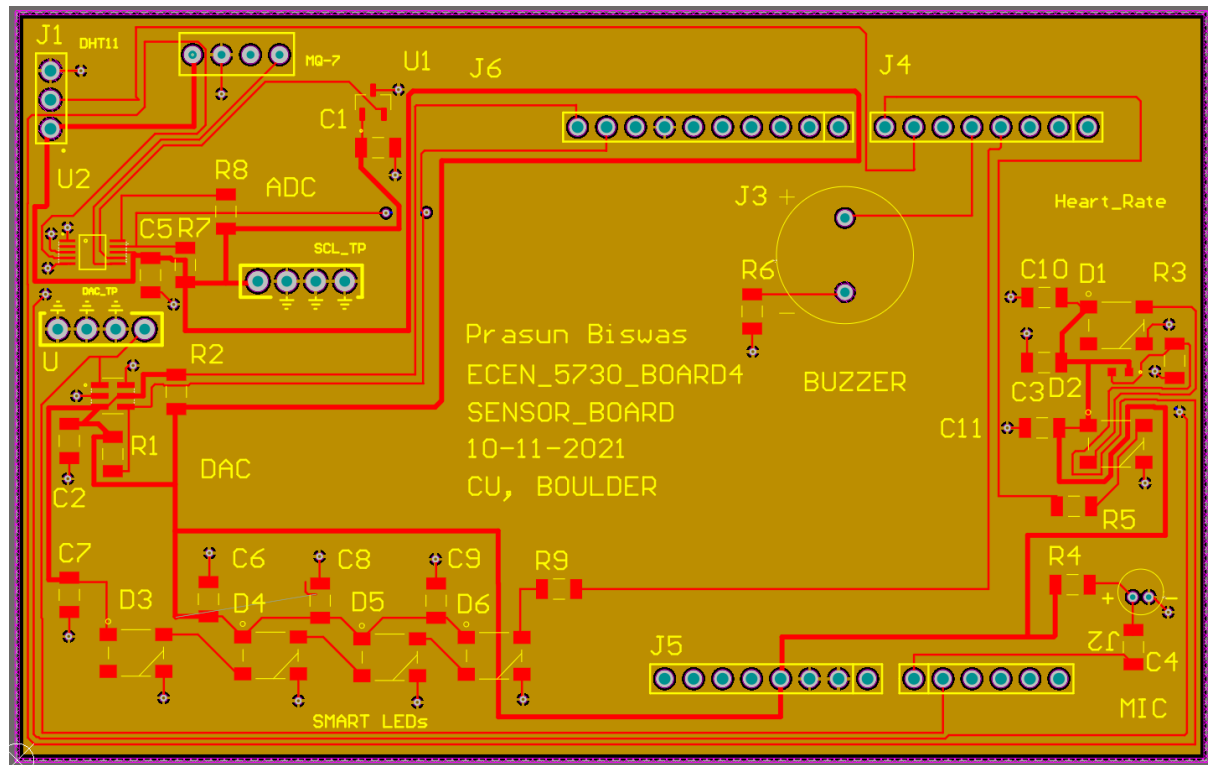

Finally, after the sensor shield was assembled with the required components, it was time to check whether all the sensors were functioning properly or not. Different codes were run on the board for different sensors and components and moreover troubleshooting was also done when some sensors were not running or working as anticipated.

### 7. Completing the documentation.

# Schematic -

# LAYOUT-

## **Assembled and powered on board**

### **➤ Functioning Part and Observation**

- The heartbeat sensor is using two smart LEDs alongside the phototransistor using the principle of photoplethysmography (PPG). When finger is placed over the two LEDs the light scatter from the finger back to the phototransistor depends on the amount of blood flowing through the finger.
- The capacitor has been connected across to reduce the switching noise when the transistor turns on. I have used a 22 uF capacitor value and a resistor is also used alongside the circuit to convert the current passing through the phototransistor to voltage. The value of the resistor depends on the calculation done for maximum voltage (5V) and maximum current passing (500uA) hence the resistor value is taken as 10k ohms.
- The interfacing of this sensor is done using the differential reading of the sensor which is connected to the A0 and A1 pin of the 16 bit ADC. The ground path has also been connected directly from ADC ground to sensor ground.
- Finally the heartbeat detection code has been checked using running of the differential code in Arduino.

### **Plotting my heart rate on the serial plotter**

- The smart LEDs are connected to the PWM pins on the digital pin panels so that they can be programmable. 4 Smart LEDs are kept in series and 2 Smart LEDs are taken for the case of the heart beat sensor and are configured in the code separately.
- For running the Smart LEDs code I have used the NeoPixel library and tested with different example but I have used the RGBW Strand test example and configured the LED count and pin number along with brightness to make that run successfully.

### **Configured the smart LEDs**

- For the temperature and humidity readings, SimpleDHT11 library was installed in the arduino to use the example of it and measuring the DHT11 readings. I have configured the same using the correct pin number done on my board and found the temperature and humidity readings on the serial monitor.

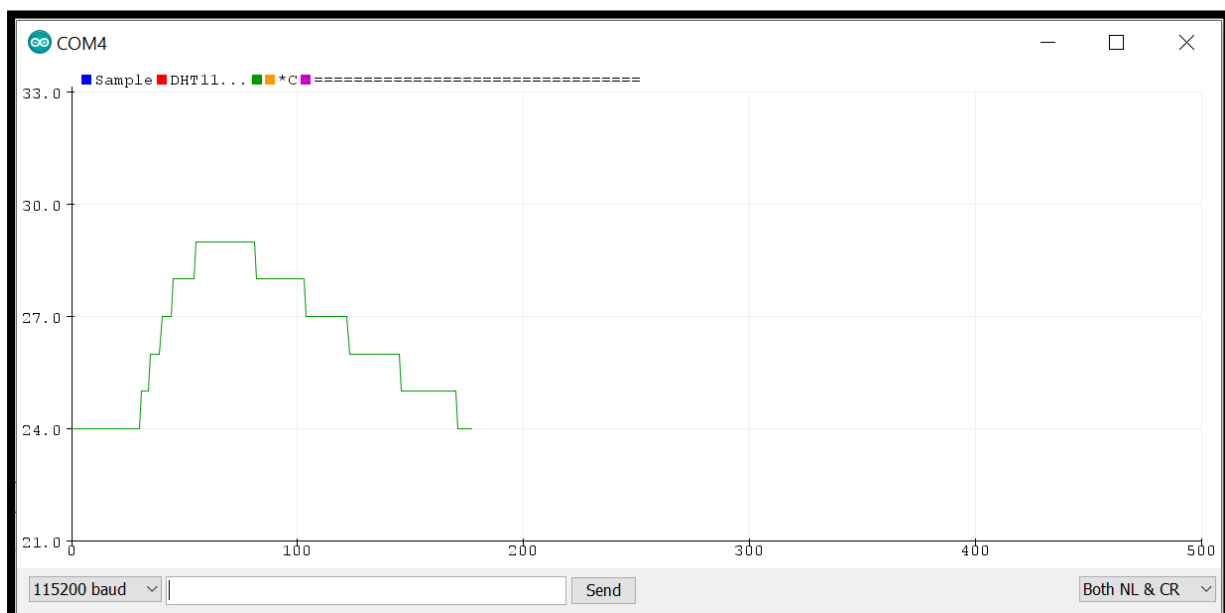

The screenshot shows the Arduino IDE with the SimpleDHT11 library code loaded. The code includes the SimpleDHT.h library, defines pinDHT11 as 6, and uses SimpleDHT11 dht11(pinDHT11). The setup function initializes the serial port at 115200 baud. The loop function prints "Sample DHT11..." and then reads the temperature and humidity. The Serial Monitor shows the following output:

```

Sample DHT11...
Sample OK: 23 °C, 17 H
Sample DHT11...
Sample OK: 23 °C, 17 H
Sample DHT11...
Sample OK: 23 °C, 17 H
Sample DHT11...
Sample OK: 23 °C, 17 H
Sample DHT11...
Sample OK: 23 °C, 17 H
Sample DHT11...
Sample OK: 23 °C, 17 H

```

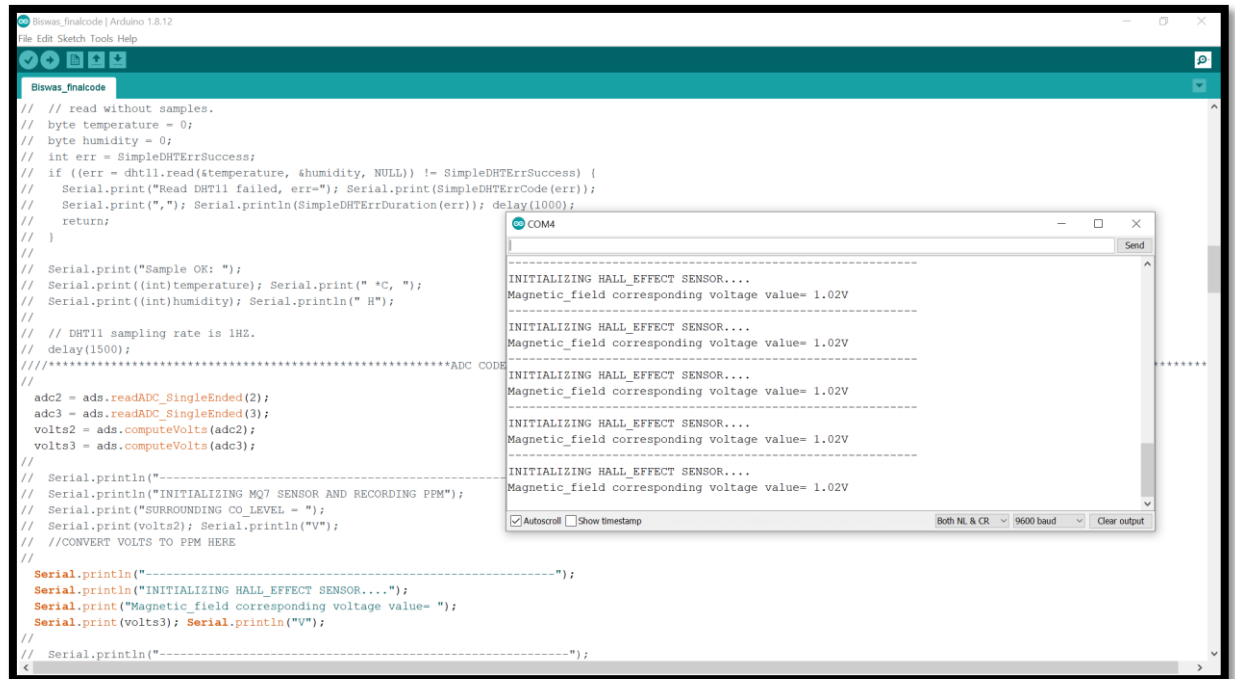

### DHT11- Temp and Humidity readings on Serial monitor

### DHT11 Temp Plotting on Serial plotter

- ✓ When a hand is placed over it for certain time the temperature increased as shown and then again decreased slowly when hand is released

- For Hall Effect sensor, we have configured it using the single ended measurement coming from the ADC. The value in voltage as output is actually equivalent to the magnetic field going around it. The value we will be getting from the sensor will be very less which is why we used the high gain parameters in ADC to get the value in some volts. Currently I am getting approx 1 Volt when there is no magnetic field which is also true as specified in the Hall Effect sensor datasheet. Later while testing, it is found that with an external sensor placed close to the Hall Effect sensor it is giving the output in some change in voltages as anticipate due to the change in magnetic field.

```

// read without samples.
// byte temperature = 0;
// byte humidity = 0;
// int err = SimpleDHTerrSuccess;
// if ((err = dht11.read(&temperature, &humidity, NULL)) != SimpleDHTerrSuccess) {
//   Serial.print("Read DHT11 failed, err="); Serial.print(SimpleDHTerrCode(err));
//   Serial.print(","); Serial.println(SimpleDHTerrDuration(err)); delay(1000);
//   return;
// }

// Serial.print("Sample OK: ");
// Serial.print((int)temperature); Serial.print(" *C, ");
// Serial.print((int)humidity); Serial.println(" H");

// // DHT11 sampling rate is 1HZ.
// delay(1500);

// *****ADC CODE *****
// adc2 = ads.readADC_SingleEnded(2);
// adc3 = ads.readADC_SingleEnded(3);
// volts2 = ads.computeVolts(adc2);
// volts3 = ads.computeVolts(adc3);

// Serial.println("-----");
// Serial.println("INITIALIZING MQ7 SENSOR AND RECORDING PPM");
// Serial.print("SURROUNDING CO LEVEL = ");
// Serial.print(volts2); Serial.println("V");
// //CONVERT VOLTS TO PPM HERE

// Serial.println("-----");
// Serial.println("INITIALIZING HALL EFFECT SENSOR...");
// Serial.print("Magnetic field corresponding voltage value= ");
// Serial.print(volts3); Serial.println("V");

// Serial.println("-----");
  
```

Serial Monitor Output:

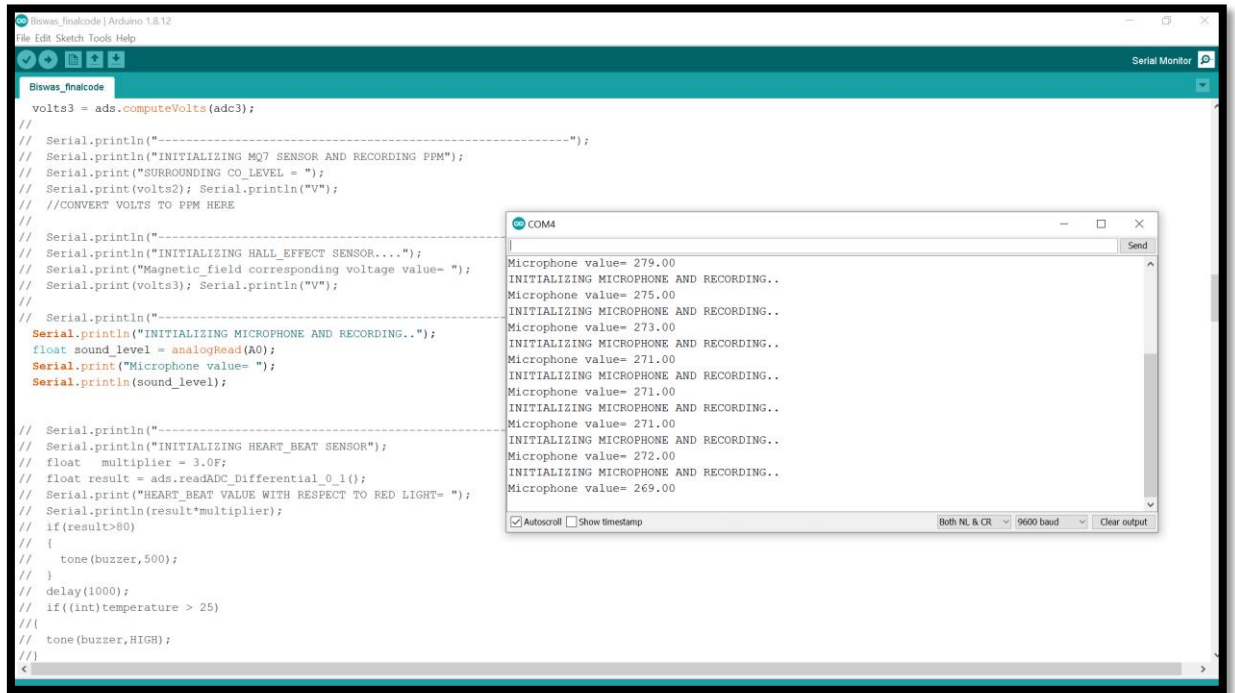

```

INITIALIZING HALL EFFECT SENSOR...
Magnetic field corresponding voltage value= 1.02V
-----
INITIALIZING HALL EFFECT SENSOR...
Magnetic field corresponding voltage value= 1.02V
-----
INITIALIZING HALL EFFECT SENSOR...
Magnetic field corresponding voltage value= 1.02V
-----
INITIALIZING HALL EFFECT SENSOR...
Magnetic field corresponding voltage value= 1.02V
-----
INITIALIZING HALL EFFECT SENSOR...
Magnetic field corresponding voltage value= 1.02V
  
```

### Hall Effect sensor reading on Serial Monitor

- The buzzer is connected to the PWM pin on the digital pin header- (Pin 4). The reason behind using that is getting the modulated digital signal at a modulated frequency if we want to. I am using the tone function in arduino to start it for some time at 5 KHz depending on a threshold value of the temperature and humidity I get.
- The microphone is connected to the analog pin A0. It is being read directly using the analogRead function in arduino.

### Microphone value on serial monitor

### Microphone value on serial Plotter

- The CO sensor (MQ7) is also connected to one of the ADC pin and is also measured using single ended measurement. The ADC value we are getting are computed to volts using compute volt function and later mapped to ppm values with some calculations based on the range of the CO sensor.

```

// Blower_finalcode
// Serial.print((int)humidity); Serial.println(" H");
//
// // DHT11 sampling rate is 1Hz.
// delay(1500);
//
// *****ADC CODE FOR MQ7, HALL_EFFECT SENSOR, AMBIENT LIGHT SENSOR*****
//
// adc2 = ads.readADC_SingleEnded(2);
// adc3 = ads.readADC_SingleEnded(3);
// volts2 = ads.computeVolts(adc2);
// volts3 = ads.computeVolts(adc3);
//
// Serial.println("-----");
// Serial.println("INITIALIZING MQ7 SENSOR AND RECORDING PPM");
// Serial.print("SURROUNDING CO_LEVEL = ");
// Serial.print(volts2); Serial.println("V");
// //CONVERT VOLTS TO PPM HERE
//
// sensorValue = ads.readADC_SingleEnded(2);
// sensor_volt = sensorValue/1024*5.0;
// RS_gas = (5.0-sensor_volt)/sensor_volt;
// ratio = RS_gas/R0; //Replace R0 with the value found using the sketch
// float x = 1538.46 * ratio;
// float ppm = pow(x,-1.709);
// Serial.println("INITIALIZING MQ7 SENSOR AND RECORDING PPM");
// Serial.print("SURROUNDING CO_LEVEL = ");
// Serial.print(ppm);
// Serial.println("PPM ");
// delay(1000);
//
// Serial.println("-----");
// Serial.println("INITIALIZING HALL_EFFECT SENSOR....");
// Serial.print("Magnetic_field corresponding voltage value= ");
// Serial.print(volts3); Serial.println("V");
//
// Serial.println("-----");
  
```

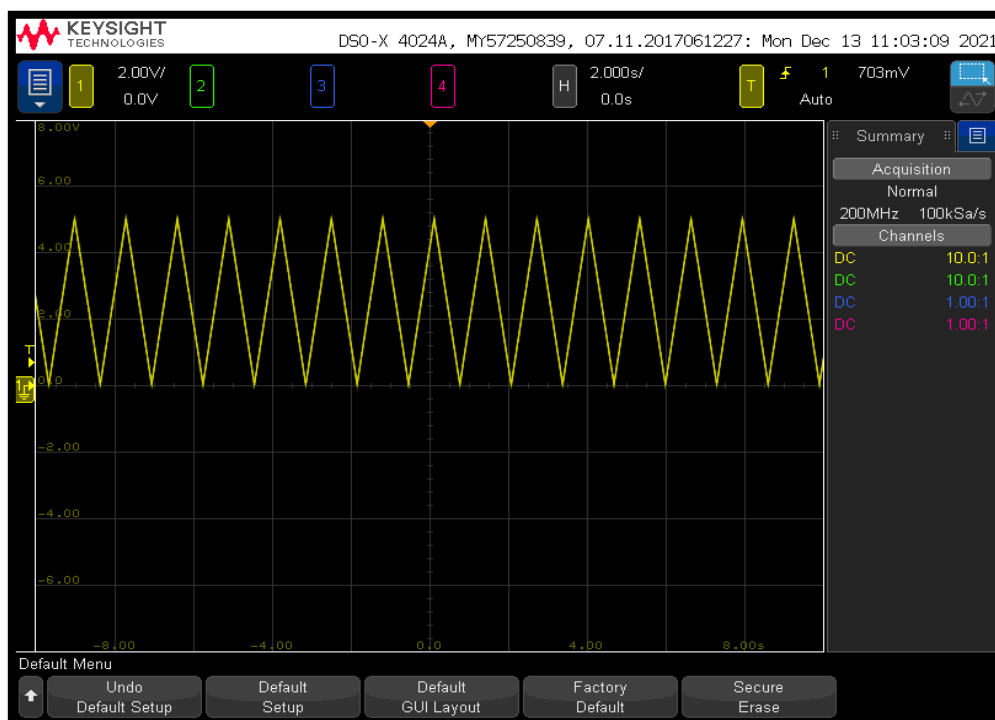

Serial Monitor Output:

```

SURROUNDING CO_LEVEL = 2.72PPM
INITIALIZING MQ7 SENSOR AND RECORDING PPM
SURROUNDING CO_LEVEL = 2.72PPM
INITIALIZING MQ7 SENSOR AND RECORDING PPM
SURROUNDING CO_LEVEL = 2.72PPM
INITIALIZING MQ7 SENSOR AND RECORDING PPM
SURROUNDING CO_LEVEL = 2.72PPM
INITIALIZING MQ7 SENSOR AND RECORDING PPM
SURROUNDING CO_LEVEL = 2.75PPM
INITIALIZING MQ7 SENSOR AND RECORDING PPM
SURROUNDING CO_LEVEL = 2.75PPM
INITIALIZING MQ7 SENSOR AND RECORDING PPM
SURROUNDING CO_LEVEL = 2.75PPM
INITIALIZING MQ7 SENSOR AND RECORDING PPM
SURROUNDING CO_LEVEL = 2.75PPM
  
```

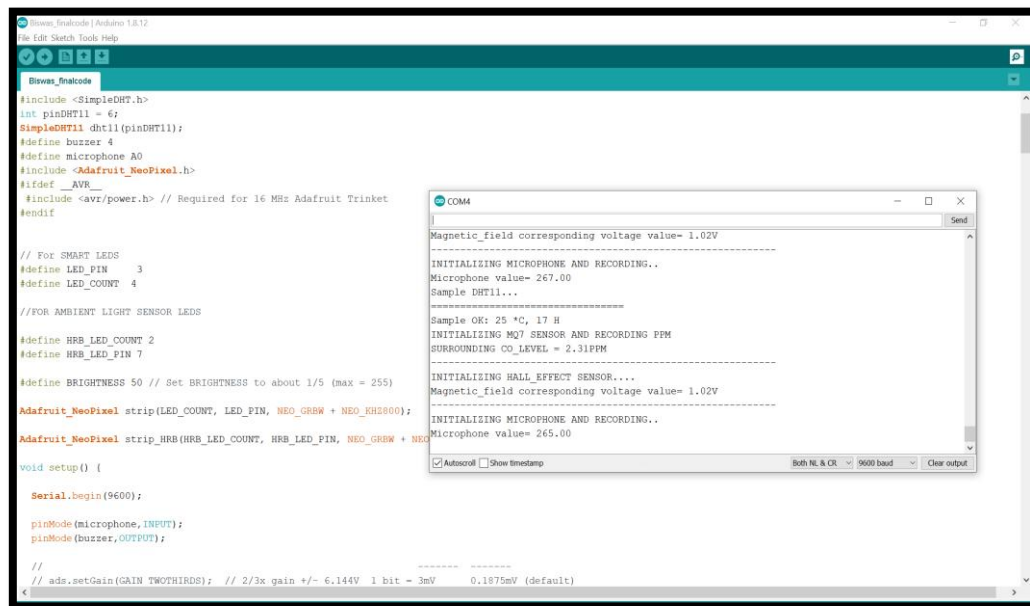

### Reading MQ7 values on Serial Monitor

- The DAC output is connected to one of the analog pin and with respect to the code uploaded; a triangular wave was generated and can be seen on the scope as well.

### DAC output on Analog pin

Finally all the sensors were integrated together in one single code except the DAC and the output is shown on the serial monitor.

The screenshot shows the Arduino IDE with a code editor on the left and a serial monitor on the right. The code editor displays the final integrated code for the project, which includes headers for DHT11, NeoPixel, and MQ7 sensors, and defines for various pins and variables. The serial monitor shows the output of the code, including initialization messages and sensor readings.

```
#include <SimpleDHT.h>
int pinDHT11 = 6;
SimpleDHT11 dht11(pinDHT11);
#define buzzer 4
#define microphone A0
#include <Adafruit_NeoPixel.h>
#ifdef __AVR__
#include <avr/power.h> // Required for 16 MHz Adafruit Trinket
#endif

// For SMART LEDs
#define LED_PIN 3
#define LED_COUNT 4

//FOR AMBIENT LIGHT SENSOR LEDS
#define HRB_LED_COUNT 2
#define HRB_LED_PIN 7

#define BRIGHTNESS 50 // Set BRIGHTNESS to about 1/5 (max = 255)
Adafruit_NeoPixel strip(LED_COUNT, LED_PIN, NEO_GRB + NEO_KHZ800);
Adafruit_NeoPixel strip_HRB(HRB_LED_COUNT, HRB_LED_PIN, NEO_GRB + NEO_KHZ800);

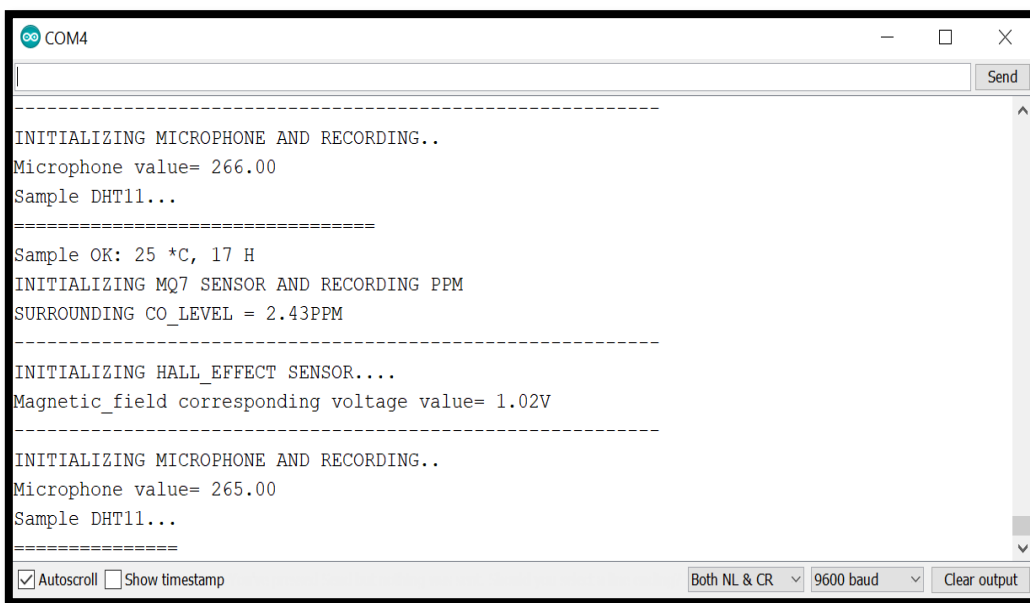

void setup() {
  Serial.begin(9600);

  pinMode(microphone, INPUT);
  pinMode(buzzer, OUTPUT);

  // -----
  // ads.setGain(GAIN_TWOTHIRDS); // 2/3x gain +/- 6.144V 1 bit = 3mV 0.1875mV (default)
}
```

The serial monitor output shows the following sequence of events:

```
Magnetic_field corresponding voltage value= 1.02V
-----
INITIALIZING MICROPHONE AND RECORDING..
Microphone value= 267.00
Sample DHT11...
=====
Sample OK: 25 *C, 17 H
INITIALIZING MQ7 SENSOR AND RECORDING PPM
SURROUNDING CO_LEVEL = 2.31PPM
-----
INITIALIZING HALL_EFFECT SENSOR....
Magnetic_field corresponding voltage value= 1.02V
-----
INITIALIZING MICROPHONE AND RECORDING..
Microphone value= 265.00
```

This screenshot is a closer view of the serial monitor output, showing the same sequence of initialization and sensor readings as the previous image.

```
INITIALIZING MICROPHONE AND RECORDING..
Microphone value= 266.00
Sample DHT11...
=====
Sample OK: 25 *C, 17 H
INITIALIZING MQ7 SENSOR AND RECORDING PPM
SURROUNDING CO_LEVEL = 2.43PPM
-----
INITIALIZING HALL_EFFECT SENSOR....
Magnetic_field corresponding voltage value= 1.02V
-----
INITIALIZING MICROPHONE AND RECORDING..
Microphone value= 265.00
Sample DHT11...
=====
```

## SENSOR READINGS-

**Emphasizing on what worked for me and what was a mistake that could be done better the next time.**

- In this particular board design I have made two errors:

Firstly, while connecting the decoupling capacitors to the smart LEDs I somehow put that 5v in series with capacitor which was further not allowing the smart LEDs to start after programming because it was not getting the voltage at all. For now I have removed that capacitor and shorted that line using soldering and made those smart LEDs working. I have also corrected that in schematics and layout.

Secondly, I have not made a proper connection from SCL pin of ADC and DAC to the SCL pin on the header which is why even when keeping the shield above the arduino board and checking for the I2C communication the clock signal was not showing a proper output as anticipated. So after debugging that, I had to solder a jumper wire from the SCL pin of ADC and connect that to the SCL pin on the arduino directly to make it functioning properly.

- Apart from that while soldering I found it a bit difficult to solder the components on the left branch of the board because I have placed the components in very close proximity to each other. I would make sure that I should keep some minimal distance between some components so that it does not create any problem while soldering.
- In addition, I also forgot to add an indicator LED on the board which needed to be added to make sure that the board was getting powered correctly when putting the sensor shield on my arduino.
- Finally, I feel I should also have planned a bit better to place the sensors and components at a much better distance especially the heartbeat sensor because sometimes it was getting difficult to put my finger and take measurements because of the male headers on the both sides which was somehow creating an obstruction.
